

Norway’s Exports to the U.S., and What the New Tariff Puts at Stake

</> Code ▼

A short applied data-analysis case study

Background

In late July 2026, the United States imposed an additional 12.5% tariff on Norwegian goods, replacing the temporary 10% global tariff that expired on 24 July 2026. The U.S. justified the higher rate under a Section 301 investigation into forced labour in global supply chains. The Norwegian government has publicly rejected that justification.¹

The OECD’s 2026 Economic Survey of Norway characterizes the country as relatively insulated from U.S. trade policy, since the U.S. takes well under 4% of Norway’s total exports.² The numbers below sit inside that picture. While aggregate exposure is low, some industries will, naturally, have greater exposure than others.

The tariff is barely a month old at the time of writing, and SSB’s trade statistics lag by about a month. There is not yet any meaningful *post-tariff* data to analyse. Instead of forcing a before/after analysis with lacking data, this case study aims at answering the following questions:

1. **How much**, and in which industries, does Norway export to the U.S., and how dependent is each industry on that specific market?
2. **How stable is that trade normally**, seasonally and otherwise, before any policy shock, so a future change can be judged against a real baseline?
3. **How much is actually at stake**: will this new tariff account for meaningful change in exports?

Data

Source: Statistics Norway (SSB), StatBank Table [08806, External trade in goods, by commodity group, country, month and imports/exports](#). Data are licensed under [CC BY 4.0](#).

Industries are classified using the UN’s [Standard International Trade Classification \(SITC\)](#) at the 1-digit level. This is broad enough to read at a glance and granular enough to show which sectors are exposed to the tariff.

Three SSB extracts, same commodity/exports settings, differing in country and time span, plus one exchange rate series pulled live:

File	Country	Months	Used for
exports_us_monthly.xlsx	United States	Jan 2025 to present	Main totals, share
exports_total_monthly.xlsx	All countries	Jan 2025 to present	US share of Norway’s total exports
exports_us_monthly_long.xlsx	United States	Jan 2018 to present	Seasonal baseline

The exchange rate series (NOK per USD, monthly average) is pulled directly from Norges Bank’s open data API, series [EXR/M.USD.NOK.SP](#), at render time, rather than from a downloaded file. It reflects whatever Norges Bank has published as of whenever the script last ran.

Tidied in [scripts/00_helpers.R](#) (shared parsing logic) and [scripts/01_wrangle_exports.R](#), [02_wrangle_share_of_total.R](#), [03_wrangle_seasonal.R](#), [05_wrangle_exchange_rate.R](#).

► Code

How much does each industry export to the U.S.?

Total exports and export share, most recent 12 months, sorted by value. Although one industry may dominate Norway’s total exports to the US, it does not necessarily have a correspondingly large exposure to the US market. More on this below.

► Code

Norway's exports to the U.S., by industry

Figure 1: Norway’s exports to the U.S. by industry: value and share, most recent 12 months

How dependent is each industry on the U.S. market?

A different question from the one above. Instead of “Which industry accounts for the largest share of Norwegian exports to the US?”, it is asking “What share of each industry’s total exports is going to the US?”. It is a reflection of each industry’s exposure to the US.

► Code

How exposed is each industry to the U.S. market specifically?

Figure 2: Share of each industry’s total (worldwide) exports that goes to the U.S., most recent 12 months

How volatile is this trade normally?

Before drawing any conclusion from a future dip or spike, a baseline for normal month-to-month variation is needed. Some industries (mineral fuels, for instance) move on large one-off shipments even with no policy change involved; others (food) are steadier.

The chart marks two dates: **2 April 2025** (“Liberation Day”), when the U.S. first announced broad reciprocal tariffs on nearly every country including Norway, and **24 July 2026**, the tariff this case study covers. The first shows what a tariff shock looks like in this data. The second has too few months of data so far for comparison.

► Code

Norway's monthly exports to the U.S., by industry

Dashed lines: 2 Apr 2025 (Liberation Day tariffs) and 24 Jul 2026 (current tariff). Data does not yet cover a meaningful window after the second

Source: Statistics Norway, Table 08806.

Figure 3: Monthly exports to the U.S. by industry, Jan 2025 to present

A seasonally-adjusted baseline

Exports naturally rise and fall by season and vary month to month for reasons that have nothing to do with policy. To judge whether a given month is actually unusual, that ordinary variation has to be removed first, leaving only the part that cannot be explained by any “normal” pattern.

Using nine years of history (2018 to present; fewer years would not support a reliable seasonal estimate), each industry’s monthly exports are decomposed via STL (Seasonal-Trend decomposition using Loess) on the log scale into trend, seasonal, and remainder components. The remainder’s historical standard deviation defines “normal”: a month is flagged as **out of the normal range** if its remainder exceeds **2 standard deviations**, larger than seasonality and typical random variation alone would usually produce. “9 Other commodities and transactions” is excluded. It is too small and irregular for a meaningful seasonal pattern.

► Code

Actual exports vs. the seasonally-expected range

Grey band = normal range (± 2 SD of remainder). Red points = out of that range. Dashed lines: Apr 2025 and Jul 2026 tariff dates.

Figure 4: Actual vs. seasonally expected exports, 2018-present, with out-of-range months flagged

Keep in mind that crossing 2 standard deviations is not a claim of real-world significance, only that a month’s move is statistically larger than that industry’s typical noise. It is used here to calibrate expectations: even at the April 2025 tariff shock, only a handful of industries experienced “unusual exports”, and only “Food and live animals” in the negative direction. Most shocks do not flag every industry at once.

As stated in the introduction, there is sparse “post-tariff” data available at the time of writing (July is latest as of early September). The following table is basically a binary check of whether the latest month of data is out of normal range or not. As of today, all industries exhibit “normal” exports, but this can be used for future reference as new data is published.

► Code

Table 1: Status of the most recent available month against each industry’s seasonal baseline

Industry	Actual (NOK mill.)	Seasonally expected (NOK mill.)	Out of normal range?
0 Food and live animals	1048	926	No
1 Beverages and tobacco	9	8	No
2 Crude materials, inedible, except fuels	197	47	No
3 Mineral fuels, lubricants and related materials	943	628	No
4 Animal and vegetable oils, fats and waxes	101	107	No
5 Chemicals and related products n.e.s.	349	366	No
6 Manufactured goods classified chiefly by material	607	443	No
7 Machinery and transport equipment	1371	1196	No
8 Miscellaneous manufactured articles	503	439	No

It is worth noting that these industries have been operating with tariffs on exports to the US ever since “Liberation Day”, lately with a 10% rate. Most likely, the new 12.5% tariff replacing the old 10% tariff will not meaningfully shift export volumes. However, in a globalized economy, every competitive advantage/disadvantage can shift balances in the long run.

Controlling for the exchange rate

The tariff is not the only thing changing the price of Norwegian goods for US buyers. If the krone weakens against the dollar, Norwegian exports get cheaper in USD terms, which can offset some of the tariff’s effect. If the krone strengthens, the opposite happens, and the tariff compounds on top of an already-rising USD price.

► Code

NOK/USD exchange rate

Dashed lines: Apr 2025 and Jul 2026 tariff dates.

Figure 5: NOK per 1 USD, monthly average

From January 2025 to August 2026 (the most recent month Norges Bank had published as of when this was last run), the rate moved from 11.34 to 9.43 NOK per USD, a change of -16.9%. A falling NOK-per-USD rate means the dollar buys fewer

kroner, which means the krone strengthened over this window. That works against Norwegian exporters' USD-denominated competitiveness, independent of the tariff.

From the tariff month itself (9.71 NOK per USD) to the latest available month, the change is −2.9%. That is not unusually large: several single-month moves earlier in 2026, unrelated to any tariff, were similar in size or bigger.

Takeaways

Although machinery and transport equipment, and food, account for the largest share of Norway’s exports to the US, that reflects the overall size of those industries, not their exposure to US market. Animal and vegetable oils, fats and waxes is small in absolute value, but sends about a quarter of its total exports to the US, the highest share of any industry, and the least able to redirect sales elsewhere if US demand drops.

The April 2025 tariff shock pushed only a few industries outside their normal range, and only Food and live animals moved down. The current increase, from 10% to 12.5%, is smaller than that shock, and follows industries already exporting to the US under a 10% tariff since April 2025. Over the same period, the krone moved by more than that 2.5 percentage-point difference, for reasons unrelated to the tariff.

If US-bound exports fall in the months ahead, the exchange rate, order timing, and global demand could be just as much to blame as the tariff.

Notes on methodology

- **Units:** NOK million, current prices (not inflation-adjusted).
- **Industry classification:** SITC 1-digit, broad by design, for readability. A finer breakdown (2- or 3-digit SITC) would show whether, for example, farmed salmon specifically drives the seafood category.
- **“9 Other commodities and transactions”** is excluded from the seasonal analysis. Several months are recorded as zero or suppressed in the source data, and the category is under 0.03% of total exports. It is too sparse and irregular for a seasonal pattern to be meaningful.
- **Seasonal baseline method:** STL decomposition on log-transformed monthly exports, `s.window = "periodic"` (assumes a stable seasonal pattern across the 2018-present window rather than one that drifts over time). The 2018-2021 portion includes the COVID trade disruption, which will inflate the estimated “normal” variation for some industries.
- **Exchange rate is pulled live, not from a static file.** The `05_wrangle_exchange_rate.R` script queries Norges Bank’s API directly at run time (series `EXR/M.USD.NOK.SP`), so August 2026 above reflects whatever was published as of the last time the pipeline ran, not a fixed download date. Re-running it later will pick up newer months automatically.
- **Reproducibility:** re-running `scripts/01_wrangle_exports.R`, `02_wrangle_share_of_total.R`, `03_wrangle_seasonal.R`, and `05_wrangle_exchange_rate.R` after downloading updated extracts regenerates every processed CSV and every figure in this document.
